## Average Relative Yields of Soybean Tested in the Virginia Official Variety Test 2009-2011

David L. Holshouser, Extension Agronomist

Selecting high-yielding soybean varieties is one of the most important steps for profitable production. To help with variety selection, Virginia Tech conducts full-season and double-crop variety tests in five regions of the Commonwealth. These regions include the Upper and Lower Piedmont, the Upper and Lower Coastal Plain, and Eastern Shore.

Multi-year averages give greater confidence to variety performance. Data presented here is an average taken from multiple-locations over the past three growing season. The greater number of locations, the greater confidence that the variety will perform as indicated. Actual yield in bushels per acre is not listed. Instead, variety performance is represented as the average relative yield, or a percentage above or below the average yield of all varieties of the similar maturity at the same location. Average relative yield removes some of the bias that occurs with multi-year averages when varieties are not tested at each location.

Actual yield and other performance data from these tests are available at your county Cooperative Extension office or can be found on the web at [www.pubs.ext.vt.edu/category/crops.html](http://www.pubs.ext.vt.edu/category/crops.html).
