### **VIRGINIA CORN HYBRID TRIALS IN 2004**

Coordinated by Wade Thomason, Harry Behl, and Elizabeth Rucker

Department of Crop and Soil Environmental Sciences

Virginia Tech Blacksburg, VA

Other contributors: Erik Stromberg; Bobby Ashburn; Bruce Beahm; Ned Jones;  
Dave Starner; Steve Gulick; Alvin Hood; Tom Stanley; Jon Wooge; Phil Blevins

Performance trials of commercial corn hybrids were conducted at seven locations in Virginia in 2004. The Mt. Holly location consisted of an irrigated and a non-irrigated test. Test weights, grain moisture, and plot grain weights were measured with a GrainGauge® manufactured by HarvestMaster. A list of the companies participating in the trials is shown in the above table. All hybrids entered in the Virginia trials were those submitted by commercial companies. The locations at which particular hybrids were entered were specified by the company. Companies entering hybrids were charged a fee for each hybrid per location to support the Corn Performance Trials.

All locations except Orange were planted with a Wintersteiger PlotKing 2600. Orange was planted by hand and thinned to the desired population. All locations except Orange were harvested with a Massey-Ferguson 8XP plot combine. Orange was hand-harvested and shelled to obtain grain weights. Yields have been adjusted to 15.5% moisture.

### **Yield Differences**

Experimental plots vary in yield and other measurements due to location in the field and other factors which cannot be controlled. Statistics given in the tables are intended to help the reader make valid comparisons between hybrids. The magnitude of differences which may have been due to uncontrollable variation has been computed for the data and listed at the bottom of columns as the LSD (.05) (least significant difference with 95% confidence). Differences less than the LSD are assumed not to be real differences with 95% confidence.

### **Choice of Hybrids**

When making hybrid selections it is important to realize that hybrids differ in their performance under different environments. Some hybrids are more adapted to a wide range of environments. Hybrid performance may vary with year and location variations in rainfall, temperature, pests and other environmental variables. In these experiments, many hybrids have essentially the same yield, and great care should be taken in interpreting the results of a single year's tests, especially at only one location. For these reasons it is important, whenever possible, to also look at a hybrid's average across locations when making hybrid selections. Multi-year averages give even greater confidence to hybrid performance decisions. The relative yield tables compare the yield of a hybrid to the average yield of all hybrids in the test. These tables are an excellent summary of yield potential compared to other hybrids.

**2004 VIRGINIA CORN HYBRID PLOT INFORMATION**

\* Relative yield is calculated by dividing the yield of a hybrid by the average yield of all hybrids of all maturities at that location. A hybrid with a relative yield of 105 was 5% above the average of all hybrids at that location. The value of 105 is not a yield but a value relative to all other yield values at that location. Relative yields are listed in order of descending mean values.

**Table 2. Two Year Average RELATIVE YIELD\* (2003-2004) of corn hybrids entered in three or more locations each year.\***

\* Relative yield is calculated by dividing the yield of a hybrid by the average yield of all hybrids of all maturities at that location. A hybrid with a relative yield of 105 was 5% above the average of all hybrids at that location. The value of 105 is not a yield but a value relative to all other yield values at that location. Relative yields are listed in order of descending mean values. A hybrid did not have to be entered in the same three locations each year to appear in this table.

**Table 3. Three Year Average RELATIVE YIELD\* (2002-2004) of corn hybrids entered in three or more locations each year.\***

CORN (*Zea mays*)

Gray leaf spot; *Cercospora zeae-maydis*

E. L. Stromberg and C. C. Kenley, Department of  
Plant Pathology, Physiology & Weed Science,  
Virginia Polytechnic Institute and State University,  
Blacksburg, VA 24061-0331

**Resistance and agronomic characters of corn hybrids under natural gray leaf spot disease pressure, Montgomery Co., VA, 2004.**

Gray leaf spot disease ratings, grain harvest moisture, bushel weights, and grain yields were obtained for 26 corn hybrids and a known high-yielding susceptible check hybrid, Pioneer Brand 3394 (highlighted in gray in the table below), grown under heavy gray leaf spot disease pressure on VPI&SU's Whitethorne-Kentland Experimental Farm, Montgomery Co., VA. Prior to planting on a Hayter silt loam, pH 6.7, a fertilizer containing 200 lb/A N, 45 lb/A P and 25 lb/A K was broadcast. The experimental design was a randomized complete block replicated four times with plots consisting of four 25-ft rows spaced 30 in. apart and seeded at a rate of 25,000 seeds/A. The plots were no-tillage planted on 7 May into a field continuously cropped to corn since 1986 and abundantly covered with corn debris naturally infested with *Cercospora zeae-maydis*, the causal agent of gray leaf spot. Leaf blighting or gray leaf spot (GLS) reaction was assessed three times and is reported as a GLS Severity Index (0-5) read in 0.1 units. Ratings were made on plants from the middle two rows of plots, excluding plants adjacent to ends of plots. Hybrids were also rated for percentage of stalks lodged just prior to harvest, grain moisture at harvest, bushel weight, and grain yield adjusted to 15.5% moisture. Grain was mechanically harvested on 28 Oct with a Massey Ferguson 8XP plot combine.

Moisture in the soil profile at planting and weather for thirty days after planting provided conditions favorable for vigorous stand establishment. GLS lesions were first observed on the lower leaves of susceptible hybrids by late June. From late June through September, temperatures were mild to warm with abundant rainfall. These conditions were moderately favorable for disease development. GLS lesions had moved to the ear leaf and above on the more susceptible hybrids by 24 Jul and to the top of these hybrids by 12 Aug. Significant differences in GLS ratings among hybrids were apparent at all rating periods. At harvest, statistically significant differences among hybrids occurred in grain yield, grain moisture at harvest, and bushel weights. Generally those hybrids that blighted least had the higher yields. The susceptible check hybrid, Pioneer Brand 3394, the most heavily blighted, ranked 27<sup>th</sup> for grain yield of the 27 hybrids evaluated and yielded 68.4 bushels less than the highest yielding hybrid in the test.
